(54) Title: **SUBSTITUTED PHENYL FARNESYLTRANSFERASE INHIBITORS**

(57) Abstract: Compounds of formula (I) or pharmaceutically acceptable salts thereof, inhibit farnesyltransferase. Methods for making the compounds, pharmaceutical compositions containing the compounds, and methods of treatment using the compounds are disclosed.

SUBSTITUTED PHENYL FARNESYLTRANSFERASE INHIBITORS

5

Technical Field

The instant invention provides substituted phenyl compounds which inhibit farnesyltransferase, methods for making the compounds, pharmaceutical compositions
10 containing the compounds, and methods of treatment using the compounds.

Background of The Invention

Ras oncogenes are the most frequently identified activated oncogenes in human tumors, and transformed protein Ras is involved in the proliferation of cancer cells. The Ras
15 must be farnesylated by farnesyl pyrophosphate before this proliferation can occur, and farnesylation of Ras by farnesyl pyrophosphate is effected by protein farnesyltransferase. Inhibition of protein farnesyltransferase, and thereby farnesylation of the Ras protein, blocks the ability of transformed cells to proliferate.

Activation of Ras and related proteins which are farnesylated also partially mediates
20 smooth muscle cell proliferation (*Circulation*, I-3: 88 (1993)). Inhibition of protein isoprenyl transferases, and thereby farnesylation of the Ras protein, also aids in the prevention of intimal hyperplasia associated with restenosis and atherosclerosis, a condition which compromises the success of angioplasty and surgical bypass for obstructive vascular lesions.

Because of this pivotal role played by farnesyltransferase in tumor formation and
25 metastasis, compounds such as those reported in WO 97/36897, WO 97/36881, WO 97/36875, WO 97/36901, WO 99/17777, WO 99/18096, WO 99/20609, WO 99/27928, WO 99/27933, WO 99/27929, WO 99/28313, and WO 99/28314 have been the subject of current research.

However, there is still an ongoing need for farnesyltransferase inhibitors with
30 modified or improved profiles of activity.

According to methods of treatment, the compounds of the instant invention can be useful for the prevention of metastases from the tumors described above either when used alone or in combination with radiotherapy and/or other chemotherapeutic treatments conventionally administered to patients for treating cancer. When using the compounds of the instant invention for chemotherapy, the specific therapeutically effective dose level for
30 any particular patient will depend upon factors such as the disorder being treated and the severity of the disorder; the activity of the particular compound used; the specific composition employed; the age, body weight, general health, sex, and diet of the patient; the time of administration; the route of administration; the rate of excretion of the compound employed; the duration of treatment; and drugs used in combination with or coincidentally with
35 the compound used. For example, when used in the treatment of solid tumors, compounds of the instant invention can be administered with chemotherapeutic agents such as alpha

interferon, COMP (cyclophosphamide, vincristine, methotrexate, and prednisone), etoposide, mBACOD (methotrexate, bleomycin, doxorubicin, cyclophosphamide, vincristine, and dexamethasone), PRO-MACE/MOPP (prednisone, methotrexate (w/leucovin rescue), doxorubicin, cyclophosphamide, taxol, etoposide/mechlorethamine, vincristine, prednisone, and procarbazine), vincristine, vinblastine, angiostatin, TNP-470, pentosan polysulfate, platelet factor 4, angiostatin, LM-609, SU-101, CM-101, Techgalan, thalidomide, SP-PG, and the like. The chemotherapeutic effect of parenterally administered compounds can be prolonged by slowing their absorption. One way to slow the absorption of a particular compound is administering injectable depot forms comprising suspensions of crystalline, amorphous, or otherwise water-insoluble forms of the compound. The rate of absorption of the compound is dependent on its rate of dissolution which is, in turn, dependent on its physical state. Another way to slow absorption of a particular compound is administering injectable depot forms comprising the compound as an oleaginous solution or suspension. Yet another way to slow absorption of a particular compound is administering injectable depot forms comprising microcapsule matrices of the compound trapped within liposomes, microemulsions, or biodegradable polymers such as polylactide-polyglycolide, polyorthoesters or polyanhydrides. Depending on the ratio of drug to polymer and the composition of the polymer, the rate of drug release can be controlled.

Transdermal patches also provide controlled delivery of the compounds. The rate of absorption can be slowed by using rate controlling membranes or by trapping the compound within a polymer matrix or gel. Conversely, absorption enhancers can be used to increase absorption.

Determination of Biological Activity

Farnesyltransferase Inhibition

Farnesyltransferase (FTase) or geranylgeranyltransferase I (GGTase I) fractions were isolated from bovine brains and purified by a series of methods which separate FTase from GGTase I and GGTase I from GGTase II. The methods involved a partial purification of all three enzymes by precipitation from a beef brain homogenate with 30% to 50% saturated

(NH₄)₂SO₄ followed by chromatography on DEAE Sepharose. A Hydrophobic Interaction Chromatography (HIC) media, Fractogel-Phenyl (EM Industries) was used to separate FTase from GGTase; and chromatography of each enzyme on MonoQ (Pharmacia) resulted in further purification of the enzymes. The catalytic purity of each enzyme was assayed separately with substrate acceptor proteins specific for that enzyme. After quickly freezing in liquid nitrogen, the various prenyl transferases were stored at -80 °C.

Bovine FTase was assayed at 37 °C for 30 minutes in a volume of 100 µL containing 44 mM HEPES, pH 7.4, 26 mM MgCl₂, 4.4 mM DTT, 18 mM KCl, 0.009% Triton X-100, 256 nM [³H]-farnesyl pyrophosphate, triammonium salt ([³H]-FPP, 759 GBq/mmol, New England Nuclear), 100 nM biotin-K-ras peptide (American Peptide Company), and FTase (12.5 µg/mL total protein). Reactions are initiated by the addition of FTase and stopped by the addition of 75 µL of a 1.43 mg/mL suspension of streptavidin SPA (Scintillation Proximity Assay) beads (Amersham) in 0.2M sodium phosphate, pH 4, containing 1.5M MgCl₂, 0.5% BSA and 0.05% sodium azide. The quenched reactions stood for 1 hour before analysis in a Packard TopCount scintillation counter. Purified compounds were dissolved in 100% ethanol and diluted 10-fold into the assay. The percent inhibition of the compounds of the instant invention at 10⁻⁶ M was then measured.

The percent inhibition of representative compounds of the instant invention are shown in Table 1.
